Jan. 7 — Motivation for Algebraic Number Theory

1.1 Motivation: Fermat's Last Theorem

Theorem 1.1 (Fermat's last theorem[1]). *$x^n + y^n = z^n$ has no nonzero integer solutions when $n \geq 3$.*

Remark. The $n = 3$ case was solved by Euler, and the $n = 4$ case was solved by Fermat. So we will assume $n \geq 5$. We can also assume n is prime, since if $n = pm$, then we can instead consider

$$(x^m)^p + (y^m)^p = (z^m)^p.$$

Thus any nonzero solution to $x^n + y^n = z^n$ also yields a nonzero solution to $x^p + y^p = z^p$. So let $p \geq 5$ be prime, and let $\zeta = \zeta_p$ be a primitive pth root of 1. Then consider

$$x^p + y^p = (x + y)(x + \zeta y)(x + \zeta^2 y) \dots (x + \zeta^{p-1} y) = z^p.$$

Note that $x + \zeta^j y \in \mathbb{Z}[\zeta] \subseteq \mathbb{C}$. Let us pretend for the moment that $\mathbb{Z}[\zeta]$ is a UFD.[2] One can check that

$$\gcd(x + \zeta^j y, x + \zeta^k y) = 1$$

whenever $j \neq k$. If $\mathbb{Z}[\zeta]$ were a UFD, then we could conclude that

$$x + y\zeta = u\alpha^p$$

for some $u \in \mathbb{Z}[\zeta]^\times$ and $\alpha \in \mathbb{Z}[\zeta]$.[3] For the sake of illustration, suppose $u = \pm\zeta^j$ for some j. Then

$$\alpha = a_0 + a_1\zeta + \cdots + a_{p-2}\zeta^{p-2}$$

for $a_i \in \mathbb{Z}$. This gives

$$\alpha^p = a_0 + a_1 + \cdots + a_{p-2} \pmod{p},$$

using Fermat's little theorem, $\zeta^p = 1$, and the binomial theorem. So $\alpha^p = a \pmod{p}$ with $z \in \mathbb{Z}$, and

$$x + y\zeta = \pm a\zeta^j \pmod{p}$$

for some $0 \leq j \leq p - 1$. Note that $\zeta^{p-1} = -(1 + \zeta + \cdots + \zeta^{p-2})$, and one can check as an exercise that this implies $p|x$ or $p|y$. This would have proved the "first case" of Fermat's last theorem.

[1] This problem was finally resolved by Wiles-Taylor in 1995.

[2] It is far from it, and this is likely the mistake that Fermat originally made.

[3] In a UFD, if a product of relatively prime elements is a pth power, then each factor must itself be a pth power.

Remark. However, Kummer (c. 1850) observed that $\mathbb{Z}[\zeta]$ is rarely a UFD (in fact, $\mathbb{Z}[\zeta]$ is a UFD if and only if $p \leq 19$).[4] Also, when $p \geq 5$, the unit group of $\mathbb{Z}[\zeta]$ is always infinite (so that $\mathbb{Z}[\zeta]^\times \neq \{\pm\zeta^j\}$).

Theorem 1.2 (Kummer)**.** *Fermat's last theorem holds for all "regular" primes.*[5]

Remark. The first irregular prime is 37, so Kummer's method works for $3 \leq n \leq 36$.

1.2 Algebraic Integers

Remark. To resolve these issues, Kummer realized that one can replace elements of $\mathbb{Z}[\zeta]$ by "ideal elements." Later on, Dedekind look at Kummer's work and introduced the modern notion of an ideal. We will be working towards the *unique factorization of ideals into prime ideals* in certain cases.

Remark. We will work at the level of generality of Dedekind rings (as opposed to just number rings). This is because there is an analogue of such a unique factorization of ideals for function fields of curves in algebraic geometry, and this framework is general enough to capture both cases.

Definition 1.1. Let $K/\mathbb{Q}$ be a finite extension (i.e. a *number field*). Then $\alpha \in K$ is an *algebraic integer* if there exists a monic polynomial $f \in \mathbb{Z}[x]$ such that $f(\alpha) = 0$.

Theorem 1.3. *Let $A \subseteq B$ be rings and let $b \in B$. Then the following are equivalent:*

1. *b is integral over A (i.e. there exists a monic $f \in A[x]$ such that $f(b) = 0$).*
2. *$A[b]$ is a finitely generated A-module.*[6]
3. *$A[b]$ is contained in a subring $C \subseteq B$ which is finitely generated as an A-module.*

Proof. $(1 \Rightarrow 2)$ This direction is standard, one only needs powers up to $\deg f$ since $f(b) = 0$.

$(2 \Rightarrow 3)$ This direction is clear since $A[b]$ itself satisfies the desired conditions.

$(3 \Rightarrow 1)$ The idea is to argue via determinants and use the Cayley-Hamilton theorem for modules. □

Corollary 1.3.1. *Integrality is transitive, i.e. if B is integral over A and C is integral over B, then C is integral over A.*[7]

Proof. A finitely generated module over a finitely generated module is finitely generated. □

Corollary 1.3.2. *If α, β are integral over A, then $\alpha \pm \beta, \alpha\beta$ are also integral over A.*

Proof. This is because $\alpha \pm \beta, \alpha\beta \subseteq C = A[\alpha][\beta]$. □

Theorem 1.4. *The set of all algebraic integers in K (denoted $\mathcal{O}_K$) forms a subring of K.*[8]

Remark. This theorem is not obvious: Given $f(\alpha) = 0$ and $g(\beta) = 0$, one must find a polynomial h such that $h(\alpha + \beta) = 0$. It is not immediately obvious how to do this.

---

[4] Kummer made the first real progress on Fermat's last theorem in a long time.

[5] A prime p is *regular* if p does not divide the order of the *ideal class group* of $\mathbb{Z}[\zeta]$.

[6] Here $A[b]$ is the smallest subring of B containing A and b, so $A[b] = \{a_0 + a_1 b + a_2 b^2 + \cdots + a_k b_k : a_i \in A\}$.

[7] We say that B is *integral over A* if every $b \in B$ is integral over A.

[8] The ring of algebraic integers $\mathcal{O}_K$ of a number field K is called a *number ring*.

Lecture 2

Jan. 9 — Algebraic Integers and Dedekind Domains

2.1 More on Algebraic Integers

Proposition 2.1. *Suppose $\alpha, \beta \in \overline{\mathbb{Z}} \subseteq \mathbb{C}$, then $\alpha + \beta, \alpha\beta \in \overline{\mathbb{Z}}$.*[1]

Proof. First, note that every algebraic integer is an eigenvalue of some integer matrix (e.g. take the companion matrix for the minimal polynomial). So take linear maps $T_\alpha : V_\alpha \to V_\alpha$ and $T_\beta : V_\beta \to V_\beta$ which have α and β as eigenvalues, respectively. Then one can check that the map on the direct sum

$$T_\alpha \oplus T_\beta : V_\alpha \oplus V_\beta \to V_\alpha \oplus V_\beta$$

has $\alpha + \beta$ as an eigenvalue. Similarly, by looking at the map on the tensor product

$$T_\alpha \otimes T_\beta : V_\alpha \otimes V_\beta \to V_\alpha \otimes V_\beta$$

has $\alpha\beta$ as an eigenvalue. Hence we see that $\alpha + \beta, \alpha\beta \in \overline{\mathbb{Z}}$ as well. $\square$

Remark. This is a constructive proof of what we showed via finitely generated modules last time.

Lemma 2.1. *Let $\alpha \in K$ be an algebraic number. Then α is an algebraic integer, i.e. $\alpha \in \mathcal{O}_K$, if and only if the minimal polynomial of α over $\mathbb{Q}$, call it $f_\alpha \in \mathbb{Q}[x]$, has integer coefficients.*

Proof. ($\Leftarrow$) This direction is clear by the definition of an algebraic integer.

($\Rightarrow$) We need to show that if $\alpha \in \mathcal{O}_K$, then $f_\alpha \in \mathbb{Z}[x]$. By assumption, there exists some monic integer polynomial $h \in \mathbb{Z}[x]$ such that $h(\alpha) = 0$. From this, we know that $f_\alpha | h$ in $\mathbb{Q}[x]$.[2] Let $\alpha_1, \dots, \alpha_n$ be the roots of f_α with $\alpha_1 = \alpha$. Since $f_\alpha | h$, we know that $h(\alpha_i) = 0$ for every i, so $h \in \mathbb{Z}[x]$ implies that $\alpha_i \in \overline{\mathbb{Z}}$ for each i. Thus the coefficients of f_α are elementary symmetric functions of the α_i,[3] so

$$f_\alpha \in (\overline{\mathbb{Z}} \cap \mathbb{Q})[x].$$

Thus it suffices to show that $\overline{\mathbb{Z}} \cap \mathbb{Q} = \mathbb{Z}$ to conclude the result. For this, suppose $r/s \in \mathbb{Q}$ is the root of

$$x^n + a_{n-1}x^{n-1} + \cdots + a_1 x + a_0 \in \mathbb{Z}[x].$$

[1] Here $\overline{\mathbb{Z}}$ is the set of algebraic integers.

[2] Note that it suffices to show that $f_\alpha | h$ in $\mathbb{Z}[x]$, so alternatively, a suitable version of Gauss's lemma immediately implies the desired result.

[3] These operations preserve the notion of being an algebraic integer.

We can assume $(r, s) = 1$ without loss of generality.[4] Plugging in, we obtain

$$(r/s)^n + a_{n-1}(r/s)^{n-1} + \cdots + a_1(r/s) + a_0 = 0.$$

Clearly denominators by multiplying by s^n, we obtain

$$r^n + a_{n-1}sr^{n-1} + \cdots + a_1 s^{n-1} r + a_0 s^n = 0$$

The right-hand side is divisible by s and every term on the left-hand side except r^n is divisible by s, so we must have $s|r^n$. Since $(r, s) = 1$, this implies that $s = \pm 1$, i.e. $r/s \in \mathbb{Z}$. □

Example 2.0.1. For $K = \mathbb{Q}$, we have $\mathcal{O}_K = \mathbb{Z}$. This follows from the previous lemma since the minimal polynomial of $a \in \mathbb{Q}$ is $x - a$, which has integer coefficients precisely when $a \in \mathbb{Z}$.

Example 2.0.2. Let $K = \mathbb{Q}(\sqrt{d})$, i.e. K is *quadratic number field*. Clearly $\mathbb{Z}[\sqrt{d}] \subseteq \mathcal{O}_K$, but this is not always an equality. For example,

$$\phi = \frac{1+\sqrt{5}}{2} \notin \mathbb{Z}[\sqrt{5}],$$

but $x^2 - x - 1$ has ϕ as a root.

Exercise 2.1. Let d be a square-free integer and $K = \mathbb{Q}(\sqrt{d})$. Show that

$$\mathcal{O}_K = \begin{cases} \mathbb{Z}[\sqrt{d}] & \text{if } d \equiv 2, 3 \pmod 4, \\ \mathbb{Z}[(1+\sqrt{d})/2] & \text{if } d \equiv 1 \pmod 4. \end{cases}$$

Definition 2.1. Let S be a ring. If $R \subseteq S$ is a subring, then we say that R is *integrally closed* in S if whenever $\alpha \in S$ is integral over R, then $\alpha \in R$.

Remark. Recall that for a domain R, its *field of fractions* K is the localization

$$K = S^{-1}R$$

where $S = R \setminus \{0\}$. There is a natural embedding of R into K via $r \mapsto r/1$.

Lemma 2.2. *The fraction field of $\mathcal{O}_K$ is K. More precisely, for every $\alpha \in K$, there exists $m \in \mathbb{Z}$, $m \neq 0$, such that $m\alpha \in \mathcal{O}_K$.*

Proof. Since α is algebraic, there exists some monic polynomial $f_\alpha \in \mathbb{Q}[x]$ such that $f_\alpha(\alpha)$. By clearing denominators, there exists $m \in \mathbb{Z}$ such that $mf_\alpha \in \mathbb{Z}[x]$. So we have

$$m\alpha^n + b_{n-1}\alpha^{n-1} + \cdots + b_1\alpha + b_0 = 0,$$

and multiplying by m^{n-1} on both sides, we obtain

$$m^n\alpha^n + m^{n-1}b_{n-1}\alpha^{n-1} + \cdots + m^{n-1}b_1\alpha + m^{n-1}b_0 = 0,$$

which implies

$$(m\alpha)^n + b_{n-1}(m\alpha)^{n-1} + \cdots + m^{n-2}b_1(m\alpha) + m^{n-1}b_0 = 0.$$

This shows that $m\alpha$ is integral over $\mathbb{Z}$, i.e. $m\alpha \in \mathcal{O}_K$. □

[4] Here we write (r, s) to denote $\gcd(r, s)$.

Theorem 2.1. *The ring of integers $\mathcal{O}_K$ is integrally closed (in its fraction field).*

Proof. Transitivity of integrality implies that $\mathcal{O}_K$ is integrally closed in K. The theorem then follows from the fact that K is the fraction field of $\mathcal{O}_K$. $\square$

Remark. This theorem says that (it implies the second equality)

$$\mathcal{O}_K = \{\alpha \in K \mid \alpha \text{ is integral over } \mathbb{Z}\} = \{\alpha \in K \mid \alpha \text{ is integral over } \mathcal{O}_K\}.$$

2.2 Dedekind Domains

Definition 2.2. A *Dedekind domain* is a Noetherian integrally closed domain of dimension 1.

Remark. Recall that all rings in this class are commutative and have a 1. A *dimension* 1 *domain* is a domain which is not a field and in which every nonzero prime ideal is maximal. In general, the *dimension* of a ring R is the maximum length of a chain of prime ideals of the form

$$\mathfrak{p}_0 \subsetneq \mathfrak{p}_1 \subsetneq \cdots \subsetneq \mathfrak{p}_n.$$

In dimension 1, this corresponds to $(0) \subsetneq \mathfrak{p}$ being the maximum chain for every nonzero prime ideal $\mathfrak{p}$, which is equivalent to the other definition.

Remark. Our goal for now will be to show that $\mathcal{O}_K$ is a Dedekind domain.

Definition 2.3. Let k be either $\mathbb{Q}$ or $\mathbb{R}$ and V be a finite-dimensional k-vector space. A *complete lattice* in V is a discrete additive subgroup Λ of V which spans V, where discrete means that any bounded subset of Λ is finite (equivalent to being discrete in the sense of topology).

Proposition 2.2. *Let V be as above (dimension n over k) and $\Lambda \subseteq V$ an additive subgroup which spans V. Then the following are equivalent:*

1. *Λ is discrete.*
2. *Λ is generated by n elements.*
3. *$\Lambda \cong \mathbb{Z}^n$ as $\mathbb{Z}$-modules.*

Proof. ($2 \Leftrightarrow 3$) This follows by the structure theorem (Λ is torsion-free since $\Lambda \subseteq V$).

($1 \Rightarrow 2$) Suppose Λ is discrete, and let $x_1, \ldots, x_n \in \Lambda$ be a basis for V. Let Λ_0 be the $\mathbb{Z}$-module which is spanned by $x_1, \ldots, x_n$. We claim that Λ/Λ_0 is finite, which implies that Λ is also generated by n elements (exercise). To see the claim, we note that there exists an integer $M > 0$ such that if $x = \sum \lambda_i x_i \in \Lambda$ with $\lambda_i \in k$ and all $|\lambda_i| < 1/M$, then $x = 0$. This is standard and follows from all norms being equivalent in a finite-dimensional vector space and the assumption that Λ is discrete.

Now let $y_1, y_2, \ldots$ be coset representatives for Λ/Λ_0. Without loss of generality (by translating in the coset), assume each $y_i \in C$, where C is the unit cube. Cover C by M^n boxes of the form

$$\frac{m_i}{M} \leq \lambda_i < \frac{m_i + 1}{M}$$

with $m_i \in \mathbb{Z}$ and $0 \leq m_i < M$. We must have $|\Lambda/\Lambda_0| \leq M^n$, since otherwise we end up with two $y_i \neq y_j$ in the same box by the pigeonhole principle, and $y_i - y_j \in C[1/M] \cap \Lambda = \{0\}$ leads to a contradiction.

($2 \Rightarrow 1$) This proof is to be finished next class. $\square$

Theorem 2.2. *If I is a nonzero ideal in a number ring $\mathcal{O}_K$, then $\mathcal{O}_K/I$ is finite.*

Proof. The strategy is to show that if $[K:\mathbb{Q}] = n$, then $\mathcal{O}_K \cong \mathbb{Z}^n$ and $I \cong \mathbb{Z}^n$ as $\mathbb{Z}$-modules. This will imply that $\mathcal{O}_K/I$ is finite, which follows from the proof of the structure theorem. In fact, we will show that I and $\mathcal{O}_K$ are lattices in $K \cong \mathbb{Q}^n \subseteq \mathbb{R}^n$. Note that it suffices to show that $\mathcal{O}_K$ is a lattice, since it immediately follows that $I \subseteq \mathcal{O}_K$ is also discrete, hence also a lattice as I is an additive subgroup.

The proof is to be finished next class. □

Corollary 2.2.1. *A number ring $\mathcal{O}_K$ is Noetherian.*

Proof. Suppose that we have an ascending chain of ideals

$$I = I_0 \subseteq I_1 \subseteq I_2 \subseteq \dots.$$

Suppose without loss of generality that $I_0 \neq 0$. Since $\mathcal{O}_K/I$ is finite, by an isomorphism theorem we see that there are only finitely many ideals in $\mathcal{O}_K$ containing I. This implies that the chain must eventually stabilize, i.e. that $\mathcal{O}_K$ is Noetherian. □

Corollary 2.2.2. *A number ring $\mathcal{O}_K$ is 1-dimensional.*

Proof. Verify as an exercise that $\mathcal{O}_K$ is not a field. Now let $\mathfrak{p}$ be a nonzero prime ideal, so that $\mathcal{O}_K/\mathfrak{p}$ is a finite domain, hence a field. This implies that $\mathfrak{p}$ is maximal, so $\mathcal{O}_K$ is 1-dimensional. □

Theorem 2.3. *A number ring $\mathcal{O}_K$ is a Dedekind domain.*

Lecture 3

Jan. 14 — Unique Factorization of Ideals

3.1 Norm in a Field

Remark. Let $K/\mathbb{Q}$ be a finite extension of degree n. Our goal will be to define a *norm* $N_{K/\mathbb{Q}} : K \to \mathbb{Q}$ which also sends $\mathcal{O}_K \to \mathbb{Z}$. Note that there are n distinct embeddings $\sigma_1, \ldots, \sigma_n : K \to \mathbb{C}$, e.g. choose a primitive element $\theta \in K$ (so that $K = \mathbb{Q}(\theta)$) with minimal polynomial f of degree n and define $\sigma : K \to \mathbb{C}$ by sending θ to some root of f, of which there are n choices.[1]

Definition 3.1. Given a finite extension $K/\mathbb{Q}$, define the *norm* $N_{K/\mathbb{Q}} : K \to \mathbb{Q}$ by

$$N_{K/\mathbb{Q}}(x) = \prod_{i=1}^{n} \sigma_i(x),$$

where $\sigma_1, \ldots, \sigma_n : K \to \mathbb{C}$ are the n distinct embeddings of K into $\mathbb{C}$.

Exercise 3.1. Show that in fact $N_{K/\mathbb{Q}}(\gamma) \in \mathbb{Q}$. (Hint: One way is via Galois theory.)

Exercise 3.2. Define $[\gamma] : K \to K$ by $x \mapsto \gamma x$, which is a $\mathbb{Q}$-linear map. Show that $N_{K/\mathbb{Q}}(\gamma) = \det[\gamma]$.

Proposition 3.1. *We have the following properties of the norm $N = N_{K/\mathbb{Q}}$:*

1. $N(\gamma) = 0$ *if and only if* $\gamma = 0$*;*
2. *if* $\gamma \in \mathcal{O}_K$*, then* $N(\gamma) \in \mathbb{Z}$*.*

Proof. Check these properties as an exercise. □

Theorem 3.1. *A number ring $\mathcal{O}_K$ is a complete lattice in $K \cong \mathbb{Q}^n \subseteq \mathbb{R}^n$.*

Proof. We need to show that $\mathcal{O}_K$ is discrete. Note that there exists a basis $\alpha_1, \ldots, \alpha_n$ for $K/\mathbb{Q}$ such that $\alpha_i \in \mathcal{O}_K$ for every i. Now suppose otherwise that $\mathcal{O}_K$ is not discrete, so there are arbitrarily small $\lambda_1, \ldots, \lambda_n \in \mathbb{Q}$ such that $\alpha = \sum \lambda_i \alpha_i$ is nonzero and in $\mathcal{O}_K$. Then

$$N_{K/\mathbb{Q}}(\alpha) = \phi(\lambda_1, \ldots, \lambda_n)$$

for some homogeneous polynomial ϕ of degree n (since each $\sigma(\alpha) = \sum \lambda_i \sigma(\alpha_i)$). Thus if $|\lambda_i| \ll 1$, the polynomial ϕ also gets small and we can obtain $0 < |N_{K/\mathbb{Q}}(\alpha)| < 1$, a contradiction since $N_{K/\mathbb{Q}}(\alpha) \in \mathbb{Z}$. □

Corollary 3.1.1. *If $I \subseteq \mathcal{O}_K$ is a nonzero ideal, then I is also a complete lattice in $\mathbb{R}^n$.*

[1] As an example of having n embeddings, consider $\mathbb{Q}(\sqrt{2}) \subseteq \mathbb{R} \subseteq \mathbb{C}$, where we can send $\sqrt{2} \mapsto \pm\sqrt{2}$.

Proof. One needs to show that I contains a basis for $K/\mathbb{Q}$. Choose any nonzero $c \in I$ and consider $c\alpha_1, \ldots, c\alpha_n \in I$ (since I is an ideal). This will also be a basis for $K/\mathbb{Q}$ since $c \neq 0$. $\square$

Corollary 3.1.2. *We have $|\mathcal{O}_K/I| < \infty$ for every nonzero ideal $I \subseteq \mathcal{O}_K$.*

Proof. This is because $\mathcal{O}_K \cong I \cong \mathbb{Z}^n$ as $\mathbb{Z}$-modules, so the result follows by the structure theorem. $\square$

Remark. These details complete the proof from last time that $\mathcal{O}_K$ is a Dedekind domain.

Remark. The following is a preview of what we will do later in the class: We will define the *norm* of an ideal to be $N(I) = |\mathcal{O}_K/I|$. One can show that if $I = (\gamma)$, then $N(I) = N(\gamma)$. An extension of the previous techniques then lead to a proof of the finiteness of the *ideal class group*.

3.2 Unique Factorization of Ideals

Remark. Recall that for ideals $I = (\alpha_1, \ldots, \alpha_k)$ and $J = (\beta_1, \ldots, \beta_\ell)$, their *product* is $IJ = (\alpha_i\beta_j)_{i,j}$.

Example 3.1.1. Consider $R = \mathbb{Z}[\sqrt{-5}]$, which is the ring of integers $\mathcal{O}_K$ in $K = \mathbb{Q}(\sqrt{-5})$. Note that

$$6 = 2(3) = (1 + \sqrt{-5})(1 - \sqrt{-5})$$

and these elements are irreducible and not associates, so R is not a UFD. However, let

$$\mathfrak{p}_1 = (2, 1 + \sqrt{-5}), \quad \mathfrak{p}_2 = (2, 1 - \sqrt{-5}), \quad \mathfrak{p}_3 = (3, 1 + \sqrt{-5}), \quad \mathfrak{p}_4 = (3, 1 - \sqrt{-5}).$$

None of these ideals are principal, but they are all prime ideals. One can check that

$$\mathfrak{p}_1\mathfrak{p}_2 = (4, 2 - 2\sqrt{-5}, 2 + 2\sqrt{-5}, 6) = (2),$$

that $\mathfrak{p}_3\mathfrak{p}_4 = (3)$, that

$$\mathfrak{p}_1\mathfrak{p}_3 = (6, 2 + 2\sqrt{-5}, 3 + 3\sqrt{-5}, 6) = (1 + \sqrt{-5}),$$

and finally that $\mathfrak{p}_2\mathfrak{p}_4 = (1 - \sqrt{-5})$. At the level of ideals, the original equation then becomes

$$(6) = (2)(3) = (\mathfrak{p}_1\mathfrak{p}_2)(\mathfrak{p}_3\mathfrak{p}_4) = (\mathfrak{p}_1\mathfrak{p}_3)(\mathfrak{p}_2\mathfrak{p}_4) = (1 + \sqrt{-5})(1 - \sqrt{-5}).$$

In fact, the previous nonunique factorization is now the same factorization in the language of ideals.

Lemma 3.1. *Let $I_1, \ldots, I_n$ be ideals in a commutative ring R, and let $\mathfrak{p}$ be a prime ideal. Suppose that $I_1 I_2 \ldots I_n \subseteq \mathfrak{p}$. Then $I_j \subseteq \mathfrak{p}$ for some j.*

Proof. Check this as an exercise, it follows from the definition of a prime ideal. $\square$

Lemma 3.2. *Let R be a Noetherian ring, and $I \subseteq R$ be a nonzero ideal. Then there exist nonzero prime ideals $\mathfrak{p}_1, \ldots, \mathfrak{p}_r$ such that $\mathfrak{p}_1\mathfrak{p}_2 \ldots \mathfrak{p}_r \subseteq I$.*

Proof. Let Σ be the set of all I for which the lemma is false. If $\Sigma \neq \varnothing$, then since R is Noetherian, Σ has a maximal element (pick $I_1 \in \Sigma$, if it is not maximal, then we can find $I_2 \in \Sigma$ with $I_1 \subsetneq I_2$, and we obtain $I_1 \subsetneq I_2 \subsetneq \ldots$ by continuing; this chain must terminate since R is Noetherian). Let J be this maximal element. Now J cannot be prime, so there exist $a, b \in R$ such that $ab \in J$ but $a, b \notin J$. Let

$$\mathfrak{a} = (J, a) \supsetneq J \quad \text{and} \quad \mathfrak{b} = (J, b) \supsetneq J.$$

Then $\mathfrak{a} \supseteq \mathfrak{p}_1\mathfrak{p}_2 \ldots \mathfrak{p}_m$ and $\mathfrak{b} \supseteq \mathfrak{q}_1\mathfrak{q}_2 \ldots \mathfrak{q}_n$. Since $\mathfrak{ab} = (J^2, Ja, Jb, ab) \subseteq J$, we obtain

$$J \supseteq \mathfrak{ab} \supseteq \mathfrak{p}_1 \ldots \mathfrak{p}_m\mathfrak{q}_1 \ldots \mathfrak{q}_n,$$

which is a contradiction. Thus we must have $\Sigma = \varnothing$, so the lemma holds for every nonzero ideal I. □

3.3 Inverse Ideals

Example 3.1.2. Consider the problem of finding $(2)^{-1}$ in $\mathbb{Z}$. Logically, the answer should be something like $(1/2) = (1/2)\mathbb{Z} \subseteq \mathbb{Q}$, which is not an ideal in $\mathbb{Z}$.[2] This will satisfy $2((1/2)\mathbb{Z}) = \mathbb{Z}$.

Definition 3.2. Let R be an integral domain with fraction field K, and let I be a nonzero ideal in R. Then the *inverse ideal* I^{-1} of I is

$$I^{-1} = \{x \in K \mid xI \subseteq R\}.$$

Example 3.2.1. Let $R = \mathbb{Z}$ and $I = (2)$. Then we can see that

$$I^{-1} = \{x \in \mathbb{Q} \mid x(2) \subseteq \mathbb{Z}\} = \frac{1}{2}\mathbb{Z}.$$

Remark. Our goal at this point is to show that if R is Dedekind, then $II^{-1} = R$. Note that if M, N are two R-submodules of K, then their product is well-defined:

$$MN = R\text{-submodule of } K \text{ generated by } \{xy \mid x \in M, y \in N\},$$

e.g. $((1/2)\mathbb{Z})((1/3)\mathbb{Z}) = (1/6)\mathbb{Z}$. This is how we will make sense of the product II^{-1}.

Lemma 3.3. *If $I = (a)$, then $I^{-1} = (a^{-1})$ and $II^{-1} = (1) = R$.*

Proof. Check this as an exercise. □

Proposition 3.2. *If R is Dedekind, $I \neq 0$ is an ideal, and $\mathfrak{p} \neq 0$ is a prime ideal, then $\mathfrak{p}^{-1}I \neq I$.*

Proof. First consider the special case $I = R$, and we want to show that $\mathfrak{p}^{-1} \neq R$. We will find $x \in \mathfrak{p}^{-1}$ which is not in R. To do this, we will take $x = a^{-1}b = b/a$ for some $a, b \in R$. We want $(b/a)\mathfrak{p} \subseteq R$, so we should look for $b\mathfrak{p} \subseteq (a)$ with $b \notin (a)$. Let $a \in \mathfrak{p}$ be any nonzero element, and we will find a suitable b.

Since R is Noetherian, there exists $\mathfrak{p}_i$ such that $\mathfrak{p}_i \ldots \mathfrak{p}_r \subseteq (a) \subseteq \mathfrak{p}$. Without loss of generality, we can assume r is minimal. This then implies that $\mathfrak{p}_i \subseteq \mathfrak{p}$ for some i, which implies $\mathfrak{p}_i = \mathfrak{p}$ since R is 1-dimensional. Assume without loss of generality that $i = 1$, so $\mathfrak{p}_1 = \mathfrak{p}$.

If $r = 1$, then $\mathfrak{p} = (a)$, so that $\mathfrak{p}^{-1} = (a^{-1}) \neq R$ since a is not a unit. So now assume $r \geq 2$. Then

$$\mathfrak{p}_2 \ldots \mathfrak{p}_r \not\subseteq (a)$$

by the minimality of r, so there exists $b \in \mathfrak{p}_2, \ldots, \mathfrak{p}_r$ such that $b \notin (a)$. But $b\mathfrak{p} = b\mathfrak{p}_1 \subseteq (a)$, so the element $x = b/a \in \mathfrak{p}^{-1}$ but is not in R. This proves that $I = R$.

[2] Note that this is not an ideal of $\mathbb{Q}$ either since it is not closed under multiplication by elements of $\mathbb{Q}$. The inverse ideal $(2)^{-1}$ is instead a $\mathbb{Z}$-submodule of $\mathbb{Q}$.

In the general case, using the hypothesis that R is Noetherian, we can write $I = (\alpha_1, \ldots, \alpha_n)$. Assume otherwise that $\mathfrak{p}^{-1}I = I$. Then for $x \in \mathfrak{p}^{-1}$, we can write

$$x\alpha_i = \sum_{j=1}^{n} a_{ij}\alpha_j, \quad a_{ij} \in R.$$

Let $A = (a_{ij})$ and define $T = xI_n - A$. Check as an exercise that $\det T = 0$. Since $\det T$ is a monic polynomial in x with coefficients in R, we see that x is integral over R. Since R is integrally closed, we must have $x \in R$, so we get $\mathfrak{p}^{-1} = R$. This contradicts the above special case. $\square$

Remark. The key idea of the proof is Cayley-Hamilton for modules: Let R be a commutative ring and M a finitely generated R-module. Then if $JM = M$, there exists a with $1 - a \in J$ such that $aM = M$. The proof above uses a similar strategy to the proof of this statement.
